VoiceRX: speak the visit, the prescription writes itself

One-page solution pitch · Gnani hackathon · November 2026

Live demo: gnani-private-clinic-demo.vercel.app/guest (read-only guest doctor, synthetic patients)

The problem

An Indian outpatient doctor sees dozens of patients a day, often in Hinglish or a regional language. Notes are typed or handwritten after the patient leaves, prescriptions are hard to read, and the patient goes home with instructions in a language they may not read well. Once they leave, the clinic hears nothing until the next visit: missed doses, side effects and new lab reports stay invisible.

The solution

VoiceRX listens to the consultation, drafts the report and prescription for the doctor to check, and then stays with the patient on WhatsApp.

1. **Speak.** The doctor records the visit as usual, in Hinglish, Hindi, English, Tamil, Telugu or Gujarati. **Gnani** turns speech into text while they talk.
2. **Check.** VoiceRX extracts complaints, findings, diagnosis and medicines. Every line links to the words it came from, and anything unclear is asked, not guessed.
3. **Prescribe.** Medicines are matched to about 2.5 lakh Indian brands, with usual dose and food instructions filled in for the doctor to confirm.
4. **Approve.** One click produces a versioned, fingerprinted prescription PDF and a FHIR health record (the format India's ABDM uses).
5. **Follow up.** The patient gets the PDF on WhatsApp and can tap for a **Gnani voice note** of their prescription in their own language. Check-ins track doses. Questions, callback requests and uploaded lab reports come back to the doctor as tasks and a "since the last visit" summary.

Why it is different

- **The doctor stays in charge.** Nothing reaches the patient until the doctor approves, and every AI sentence shows its source.
- **Built for India.** It works in local languages and code-mixed speech, uses Indian brand names, and follows up through WhatsApp, which patients already use.
- **Closes the loop.** Most scribes stop at the note. VoiceRX carries the visit into the patient's week and back to the next consultation.

What is built and running

- A hosted doctor dashboard (FastAPI, Supabase Postgres, Vercel) with hospital, doctor and patient workspaces, recording, review, approval, PDFs and FHIR export.
- A live Meta WhatsApp bot that delivers reports, sends voice notes on request, answers from the approved report, and raises doctor tasks.
- Privacy by default: phone numbers are encrypted, sessions are server-side with CSRF protection, the webhook is signature-checked, and the demo uses synthetic data only.
- 675 automated unit tests, and a read-only guest preview for anyone to explore.

Next steps

Clinical validation on real multilingual consultations, individual doctor accounts, approved WhatsApp templates, and a pilot with a partner hospital's outpatient department.

VoiceRX is a hackathon prototype on synthetic data. It is not a certified medical device, and the clinician remains responsible for every approved prescription.
